- 1. Answer the following questions.
  - (a) (4 points) A birth-and-death Markov chain is a process with countably infinite state space and two types of transitions: births from i to i+1 and deaths from i to i-1. The transition probabilities can be defined as follows:

$$p_{ij} = \begin{cases} q_i, & \text{if } j = i - 1\\ p_i, & \text{if } j = i + 1\\ 1 - p_i - q_i, & \text{if } j = i\\ 0, & \text{otherwise} \end{cases}$$

| $q_i$ and $p_i + q_i \leq 1$ .   |
|--|
| e the transition matrix. Furthermore, give some real-world applications cand-Birth chains. |

5. Consider a machine that is capable of producing three types of parts. The state of the machine at time period n is denoted by a random variable  $X_n$  that takes values in  $S = \{0, 1, 2, 3\}$ , where 0 means the machine is idle and i = 1, 2 or 3 means the machine produces a type i in the time period. Suppose the machine's production schedule is Markovian in the sense that the next type of part it produces, or a possible idle period, depends only on its current state, and the probabilities of these changes do not depend on time. Suppose  $X_n$  is a Markov chain with the transition matrix

$$P = \begin{bmatrix} 0.1 & 0.2 & 0.2 & 0.5 \\ 0.3 & 0.4 & 0 & 0.3 \\ 0.4 & 0 & 0.4 & 0.2 \\ 0.3 & 0 & 0.2 & 0.5 \end{bmatrix}$$
